Thin films of Bi$_2$Te$_3$ and Bi$_2$Se$_3$ have been grown on deoxidized GaAs(001) substrates using molecular beam epitaxy. Cross-sectional transmission electron microscopy established the highly parallel nature of the Te(Se)-Bi-Te(Se)-Bi-Te(Se) quintuple layers deposited on the slightly wavy GaAs substrate surface and the different crystal symmetries of the two materials. Raman mapping confirmed the presence of the strong characteristic peaks reported previously for these materials in bulk form. The overall quality of these films reveals the potential of combining topological insulators with ferromagnetic semiconductors for future applications.

Recent photoemission measurements of the surfaces of topological insulators (TIs) such as Bi$_{1-x}$Sb$_x$, Bi$_2$Te$_3$ and Bi$_2$Se$_3$ have confirmed that a conducting surface state with an odd number of Dirac points exists in these materials. Theoretical models of topological insulators have predicted that this surface state should be robust and “topologically protected.” Moreover, this conducting state is naturally spin-polarized, which opens up interesting opportunities for possible applications in spintronics. The growth of such topological insulators by molecular beam epitaxy (MBE) is especially attractive because of the possibility to avoid defect formation by controlling the growth conditions. Efforts to fabricate TI thin films by MBE have included growth of the pseudo-hexagonal TI films, with the parallel nature of the Te(Se)-Bi-Te(Se)-Bi-Te(Se) quintuple layers deposited on the slightly wavy GaAs substrate surface and the different crystal symmetries of the two materials. Raman mapping confirmed the presence of the strong characteristic peaks reported previously for these materials in bulk form. The overall quality of these films reveals the potential of combining topological insulators with ferromagnetic semiconductors for future applications.
time. As shown in Fig. 1(a), usually observed in Bi$_2$Te$_3$ case (QL of Bi$_2$Te$_3$ usually survives for a longer annealing time than Bi$_2$Se$_3$), longer annealing times yielded an unreconstructed pattern with distinct features observed for GaAs [110] and [110] directions, respectively. We attribute this to the hexagonal surface symmetry of the TI layer. On the other hand, short annealing times yielded the same RHEED patterns for both GaAs [110] and [110] directions, as shown in Fig. 1(b), which is often observed for Bi$_2$Se$_3$. Note that the RHEED pattern is actually a combination of the two distinct patterns seen on the [110] and [110] directions in the long annealing case. We therefore attribute this to the coexistence of two types of hexagonal surfaces perpendicular to each other. The MBE growth of Bi$_2$Te$_3$ and Bi$_2$Se$_3$ was then performed under the condition of $T_{Te}$ (or $T_{Se}$) < $T_{substrate}$ ($300^\circ$C) < $T_{Bi}$ ($500^\circ$C) with a Se(or Te):Bi beam equivalent pressure ratio ranging from 15:1 to 25:1. While no notable differences were observed for the growth of Bi$_2$Te$_3$ and Bi$_2$Se$_3$ when carried out on substrates with or without the GaAs buffer layer, the results described here refer only to TI films grown without the buffer layers. The TI thin films were grown layer-by-layer, with typical growth rates in this work of 2 QL/min, as characterized by RHEED oscillations (data not shown). RHEED patterns shown in Fig. 1 were maintained throughout the whole growth process. It should be emphasized that the same kind of growth is also observed on the Ga-rich GaAs (001) surfaces, i.e., surfaces with a $(4 \times 6)$ RHEED pattern. We therefore attribute the growth of pseudo-hexagonal Bi$_2$Te$_3$ and Bi$_2$Se$_3$ on the GaAs (001) substrates to the weak Van der Waals coupling between the substrate and the TI films, leading to immediate strain relaxation as the interface is forming.

The film thicknesses were determined ex situ through model-fitting of the specular x-ray reflectivity (XRR), as shown by the example (thickness $\sim$68 nm) in Fig. 2. These thickness values were in reasonable agreement with the growth rates that were estimated in situ from RHEED oscillations. The standard deviation of film thickness obtained by fitting the XRR data was about 2.3 nm (3% of thickness), which suggests the root-mean-square roughness average (RMA) will be of the same order as that reported for the TI films of comparable thickness grown on other substrates.

The overall crystallinity of the TI films was initially evaluated by high resolution x-ray diffraction (HR-XRD) using the Cu $K_{\alpha1}$ radiation line. Figure 3 shows XRD patterns that were obtained from: (a) a 233-nm-thick Bi$_2$Te$_3$ film and (b) a 180-nm-thick Bi$_2$Se$_3$ film, respectively. Strong reflections only from [003]-type lattice planes are visible, which is indicative of the highly pronounced c-axis growth of the film. The full-width-half-maximum for the (0,0,6) plane indicates that the crystallinity of Bi$_2$Se$_3$ was considerably better than that of Bi$_2$Te$_3$ (108 versus 763 s). The QL thicknesses were calculated from the XRD data, giving $d_{QL} = 1.006 \pm 0.015$ nm for Bi$_2$Te$_3$ and $d_{QL} = 0.9527 \pm 0.0005$ nm for Bi$_2$Se$_3$, respectively (uncertainties correspond to $1\sigma$). Both values are consistent with the values of 1.016 nm for the bulk Bi$_2$Te$_3$ (Ref. 11) and 0.9545 nm for bulk Bi$_2$Se$_3$.

The microstructure of the films was determined using cross-section transmission electron microscopy (XTEM). Samples were prepared for TEM examination using standard mechanical polishing and argon-ion-milling, with the sample held at liquid-nitrogen temperature during the latter process in order to avoid unintentional ion-milling artifacts. Gentle handling was necessary because the TI films had a tendency to peel away from the substrate during the preparation procedure, consistent with weak bonding between the TI films and the substrate. Figure 4(a) is an XTEM image showing a region of the Bi$_2$Se$_3$ film close to the GaAs substrate surface. Despite the slightly wavy surface of the epi-ready GaAs substrate, highly parallel layers are clearly visible in the Bi$_2$Se$_3$ film, suggesting that the high crystal quality is achieved by an internal self-correction process that is occurring as the growth proceeds. Figure 4(b) shows an enlarged view of the Bi$_2$Se$_3$/GaAs interface, which illustrates the pronounced planarity of the Bi$_2$Se$_3$ lattice planes even in close proximity to the undulating GaAs surface. In addition, atomically sharp image of XTEM shows no dislocations and accumulated strain immediately above GaAs, despite the symmetry mismatch between the TI films and the GaAs (001) surface. This
observation undoubtedly confirms the rapid relaxation of strain at the interface, which is similar to what is observed on graphene and Si.\textsuperscript{3–7} We attribute such unique feature to the weak van der Waals coupling between adjacent QLs in the TI films. TEM images also confirmed that the $a$-axis of the pseudo-hexagonal TI films lies along either the [110] or the $1/210/138$ direction of the GaAs (001) substrate.

Micro Raman spectroscopy with a 532-nm excitation laser (power $0.8 \text{ mW}$) was also performed. The results, shown in Fig. 5, reveal three of the characteristic peaks for Bi$_2$Se$_3$ [at $71$ cm$^{-1}$ ($A_{1g}$), $131$ cm$^{-1}$ ($E_{2g}$), and $174$ cm$^{-1}$ ($A_{2g}$)], and two of the characteristic peaks for Bi$_2$Te$_3$ [at $102$ cm$^{-1}$ ($E_{2g}$) and $134$ cm$^{-1}$ ($A_{2g}$)]. The peaks observed in these two TI materials are consistent with the lattice vibration modes reported earlier.\textsuperscript{12} Moreover, Raman mapping showed that the positions of these Raman peaks measured within a scan area of $15 \mu m \times 15 \mu m$ vary spatially by less than $\sim 1$ cm$^{-1}$, indicating a good uniformity of the films.

In summary, even though there is mismatch between the hexagonal lattices of Bi$_2$Te$_3$ and Bi$_2$Se$_3$ topological insulators and the cubic symmetry of the GaAs (001) surface, we have grown high quality epitaxial films of Bi$_2$Te$_3$ and Bi$_2$Se$_3$ on GaAs (001) substrates. The films are highly uniform and the crystallinity is comparable to that of films grown on substrates with hexagonal surface structure. Future studies of Bi$_2$Te$_3$ and Bi$_2$Se$_3$ grown on GaAs (001) substrates should contribute towards a better knowledge of MBE growth of topological insulators, as well as opening up the opportunity for future spin-based devices that combine topological insulators with ferromagnetic semiconductors.
